## PREFACE

This investigation was conducted by the General Electric Company under Contract NAS3-19429, administered by the National Aeronautics and Space Agency, Lewis Research Center. Mr. G.K. Sievers was the NASA QCGAT Project Manager and provided technical direction for the program.

PRECEDING PAGE BLANK NOT FILMED

## ABSTRACT

The preliminary design of an engine which satisfies the requirements of a quiet, clean, general aviation turbofan (QCGAT) engine is described in this report. Also an experimental program to demonstrate performance is suggested. During the experimental program, an engine based on T700-GE-700 engine core, will be designed, built, and tested at General Electric facilities. The engine would then be shipped to the Lewis Research Center of the NASA for their evaluation.

The T700 QCGAT engine preliminary design indicates that it will radiate noise at the same level as an aircraft without engine noise, have exhaust emissions within the EPA 1981 Standards, have lower fuel consumption than is now available in comparable size engines, and have sufficient life for five years between overhauls.

QCGAT EXPERIMENTAL PROGRAM BUDGETARY COST ESTIMATE  
(Proprietary Supplement)

## INTRODUCTION

This report summarizes the work done under NASA contract NAS 3 - 19429, Quiet Clean General Aviation Turbofan (QCGAT). The work was performed according to the schedule shown in Figure 1. Task I examined selection of current turbofan technology for application to general aviation small turbofans using the T700-GE-700 turboshaft engine as a core. Task II included the preliminary design of a flight engine suitable for general aviation aircraft. Task III was the preparation of an experimental program to demonstrate operation of the turbofan engine in General Electric engine test facilities.

Individual oral presentations, summarizing results were made to NASA at the Lewis Research Center at the completion of each of the three tasks. This report documents results of the entire program.

The engine described offers small general aviation aircraft a quiet, low emission, long life, high flight-speed power plant with much lower fuel consumption than is presently available. It utilizes the latest small military helicopter core engine technology with a fan and reduction gear based on the NASA experimental Quiet Clean Short-Haul Experimental Engine (QCSEE) engine. By the time this small Quiet Clean General Aviation Turbofan (QCGAT) engine goes into service, in 1982, there will be a military base of 1800 T700-GE-700 engines produced and in service, with a total anticipated production in excess of 4700 units.

## SUMMARY

To satisfy the requirements of representative turbine-powered general aviation aircraft, General Electric selected a high by-pass ratio (10 to 1) turbofan engine using the T700-GE-700 turboshaft engine as a core. The T700-GE-700 engine is an advanced technology turboshaft engine designed for advanced helicopter applications. It is rated at 1145 kw (1536 shp) and, by its selection in advanced systems such as the Utility Tactical Transport Aircraft System (UTTAS) and the Advanced Attack Helicopter (AAH), is regarded as the current standard for advanced helicopter propulsion systems.

The T700-GE-700 engine employs turbine temperatures and other technology comparable to that of current large high by-pass engines. It has other characteristics, such as relatively high-pressure ratio, simplicity, compactness, and maintainability which make it attractive for use in a small turbofan engine. Furthermore, the T700-GE-700 engine cycle and combustor are compatible with low emissions. The size of the fan engine that results from this selection is in the 11.12 kN (2500-pound) thrust class, the lower portion of the thrust range of current business jet engines.

The by-pass 10-cycle was selected to favor low energy consumption and noise. The fan was sized and the engine rated such that a reasonable level of climb and cruise thrust can be achieved, making the engine suitable for a variety of aircraft types. Compared to current business jet turbofans, the engine is higher in by-pass ratio and lower in fan pressure ratio. The large improvement in specific fuel consumption over current engines will allow a substantial improvement in aircraft capability for a given size aircraft.

The selected fan is a scaled version of the QCSEE fixed pitch design, which will make data obtained in the QCSEE program useful for the QCGAT program. It is planned to scale the aerodynamic design directly and to change the mechanical design, including the gearing, only as appropriate to the small size of the T700-GE-700 engine turbofan. The T700-GE-700 engine low-pressure turbine can be used with only small modifications to the airfoils. The fan supercharges the T700-GE-700 engine core, but the QCGAT engine observes the design limitations of the T700-GE-700 engine and requires no structural changes. Figure 2 shows the T700 QCGAT engine. It has a new compact, low frontal area accessory gearbox, but only minor changes are required to accessories and fuel control to adapt them to turbofan operation. Composite materials are selected for several fan components, and a two-position fan discharge nozzle is included to minimize fuel consumption during cruise.

Figure 2. T700 Quiet Clean General Aviation Turbofan Engine.

The engine cycle and fan mechanical design have been selected to favor low noise levels, and noise suppression treatment is included in the fan casing. In addition, a typical nacelle configuration is presented which also includes noise suppression treatment. The total effect is to emit engine noise at levels which are very close to those of the representative aircraft alone (without the engine). This low noise level, which is about 20 dB below the current FAR 36-1969 noise rules, can be achieved by an engine design which has:

1. A fan with at least twice as many outlet guide vanes (OGV) as rotor blades.
2. A fan with at least two-chord spacing between rotor blades and OGV.
3. Low fan pressure ratio and tip speed.
4. High by-pass ratio and low core exhaust velocities.
5. Acoustic treatment.

Also low engine thrust required on approach is beneficial.

Figures 3 through 5 show current aircraft-radiated noise on takeoff, sideline, and approach. Shown also are figures of merit such as the FAR 36 noise rules and the estimated aircraft noise only. The radiated noise target for the T700 QCGAT engine is to equal or better the aircraft noise only. The figures indicate that the engine, when acoustically treated, will practically achieve that goal.

The combustion system employed in the QCGAT engine is a compact, annular configuration using air-atomizing fuel injectors in counterrotating swirlcup assemblies. A similar combustion system is employed in the TF34-GE-100 engine. Combustion system emissions levels predicted for the QCGAT engine cycle are based on engine emissions measurements from the GE12 engine (T700-GE-700 demonstrator), and the TF34-GE-100 engine, with refinements to compensate for the QCGAT engine cycle based on correlation equations similar to those developed for the NASA Clean Combustor Program.

Based on these analyses, the QCGAT engine will meet the 1981 EPA standards for Class T1 engines on  $\text{NO}_x$  and unburned hydrocarbons. Reduction of emissions of carbon monoxide from the T700-GE-700 engine combustion system, however, will be required at Idle conditions. Significant reductions in CO emissions by sector burning at Idle power have been estimated from data obtained using the techniques developed on the CF6 and F101 emissions reduction programs. A 47% reduction in CO emissions, and an 87% reduction in  $\text{C}_x\text{H}_y$  emissions are predicted, by using sector burning. The QCGAT engine will, therefore, have exhaust emissions well below the 1981 EPA standards.

Figure 3. QCGAT Flight Noise Comparisons at Takeoff.

Figure 4. QCGAT Flight Noise Comparisons at Sideline.

Figure 5. QCGAT Flight Noise Comparisons at Approach.

Table 1 is a breakdown of emissions for the various segments of the EPA class T1 Standards cycle. It shows the importance of the Idle segment of the cycle where sector burning makes a strong beneficial impact.

**TABLE 1. T700 QCGAT ESTIMATED EMISSIONS**  
(Grams/Kilograms of Fuel)

	<u>T700</u> <u>Idle</u>	<u>Idle</u> <u>With Sector</u> <u>Burning</u>	<u>Takeoff</u>	<u>Climb</u>	<u>Approach</u>
CO	43	22.8	2.0	2.4	9.3
C <sub>x</sub> H <sub>y</sub>	1.5	0.15	0.01	0.02	0.12
NO <sub>x</sub>	3.6	3.6	14.9	13.4	8.1

During the experimental program developed in Task III, an experimental engine similar to the production engine of Task II will be designed, built, and tested. The engine will have a T700-GE-700 core with geared-fan, nacelle, low, two position fan exhaust nozzle, and complete sound suppression treatment. The flow path and acoustical requirements will conform to the requirements of the production engine but the engine will not have parts of composite materials and some hardware such as the oil tank, oil coolers, and piping and valves for combustor sector burning will not be of the final flight design.

A component test will be run on the fan reduction gear, which will be loaded by a water brake, to determine its sea level performance throughout its power and speed range. Also fan blades and vanes will be vibration tested and all parts mechanically tested to assure mechanical integrity in the design. A combustor component will be tested to evaluate its emissions performance.

The experimental program includes 90 hours of engine testing in General Electric facilities in Lynn, Massachusetts, and Peebles, Ohio, using one engine. Testing will include demonstrations of thrust, low SFC, low noise and low emissions as well as mechanical integrity. At the termination of the program, 30 months after start, the experimental engine and nacelle will be delivered to Lewis Research Center of NASA for additional testing in NASA facilities.

## ENGINE SELECTION AND APPLICATION

It is generally recognized that general aviation fills an important transportation need by complementing the scheduled airlines and by serving areas not reached by normal domestic airlines flights. Both general aviation and the airlines will be adversely affected by fuel shortages and increased fuel costs. However, the relative position of general aviation for business travel may improve because of the continuation of scheduling difficulties, brought about by further reductions in the number of airline flights, which has taken place in the last several years.

In order to achieve expansion in general aviation, attention must be paid to the economic and environmental aspects of the aircraft and its propulsion. This includes low noise, low emissions and, very importantly, low fuel consumption. General Electric selected the T700 QCGAT engine to provide these qualities in a size applicable to the general aviation industry.

The T700 QCGAT engine has very low noise signatures because of the basic cycle and fan mechanical design. Low fan pressure ratio, high by-pass ratio, low core exhaust velocity, no inlet guide vanes and a low noise fan rotor/exit guide vane design are contributing factors. The low noise benefits that an aircraft installation gains from the engine are estimated for a Citation size aircraft in Table 2.

TABLE 2. T700 QCGAT (ENGINE ONLY)  
PRELIMINARY NOISE ESTIMATES - GENERAL AVIATION AIRCRAFT

Takeoff Gross Weight = 5216 kg (11,500 lb)

Condition	2 Engines		Equiv. to STOL Requirement EPNdB
	T700 QCGAT Est. EPNdB	Current FAA Rule EPNdB	
Takeoff - 6.5 km (3.5 nmi) from brake release	69 (FAR 36-24)	93	76-81
Sideline - 0.5 km (0.25 nmi)	79* (FAR 33-23)	102	83
Approach - 113 m (370 ft) at 1.85 km (1 nmi) from threshold.	81 (FAR 36-21)	102	96

\* The sideline noise estimate includes 1.5 EPNdB for aircraft fuselage shielding effects.

With the current T700-GE-700 core engine, the T700 QCGAT engine would meet the no smoke,  $C_xH_y$  and  $NO_x$  requirements and be within 28% of the CO requirement. The emissions for the T700 QCGAT engine are expected to meet the 1981 EPA Class T1 requirements with low risk as a result of sector burning at Idle.

The engine has significantly better specific fuel consumption at cruise than the best current general aviation turbofan engines. This reduction in fuel consumption allows the aircraft designer to build a smaller aircraft for a given need or permits more range from a given aircraft. An example of the savings that the T700 QCGAT engine provides is shown in Table 3, where an aircraft tailored to take advantage of the T700 QCGAT engine's low fuel consumption is compared to the Cessna Citation. A new aircraft designed to carry the same payload the same distance requires 771 kg (1700 lb) less gross weight than the Citation. Another measure of its merit is the 55% better passenger miles per pound of fuel for the T700 QCGAT powered aircraft than for the Citation. Flight characteristics of the aircraft are shown in Table 4, and the takeoff flight path is shown in Figure 6.

### T700 MILITARY ENGINE BASE AND COMMONALITY WITH QCGAT

The T700 QCGAT engine is a derivative of the T700-GE-700 turboshaft engine presently being qualified for service in the Utility Tactical Transport Aircraft Systems (UTTAS) and the Advanced Attack Helicopter (AAH). In addition, it will be certified for use in nonmilitary helicopters. Figure 7 shows the T700-GE-700 engine cross section and specification data. Both the core engine rotor and the free power turbine rotor are shown in solid black. Figures 8 and 9 show the T700-GE-700 Development program, the current status of engines shipped, and number of test hours accumulated through October, 1975.

Nearly all of the parts in the T700 QCGAT core engine come directly from the T700-GE-700 military engine. In this way, it achieves commonality with a production base of 4700 engines (minimum current estimates). The value of these common parts will be approximately 43% of the T700 QCGAT engine cost.

The common parts include:

1. Axial and centrifugal compressors
2. Combustor
3. High-pressure turbine
4. Low-pressure turbine, except airfoils
5. Exhaust frame
6. Hydromechanical control
7. Alternator
8. Exciter
9. Igniters
10. T4.5 Harness and Thermocouples
11. Fuel/Oil Coolers
12. Fuel Pump

Figure 10 shows a cross section of the engine and identifies the T700 common parts.

General Electric experience with commercial and business jet engines, which are derivatives of military engines (CF6-GE-6, CF6-GE-50, CJ805, CJ610, CF700, T58 and T64-GE-823) indicates that in addition to the unit part cost advantages due to the T700-GE-700 military engine base, there will be benefits of the continuing military product improvement programs. These will result in life, performance, quality, and reliability improvements based on the more demanding military helicopter flight experience.

Figure 10. QCGAT Engine Showing QCGAT Unique and T700-GE-70J Engine Common Parts.

## PERFORMANCE

A tentative flight envelope is shown on Figure 11. At sea level, the maximum Mach number is 0.4 which is probably higher than would be required for a quiet general aviation aircraft. The ceiling is at about 13.7 km (45,000 ft) which is appreciably higher than the 10.7 km (35,000 ft) cruise altitude which is expected, and the maximum Mach number of 0.8 is sufficiently greater than the 0.6 to 0.7 range where the aircraft will probably cruise for economical flight.

To improve fuel economy and increase climb and cruise thrust, the T700 QCGAT turbine inlet temperature is higher than that of the T700-GE-700 at corresponding part power ratings. However, take off ratings on hot days are set at the T700 maximum core RPM and  $T_{4.1}$  conditions, to provide commonality with the military engine high temperature parts.

The higher temperatures must be traded off against engine life, which is discussed in the Engine Life Analysis section of this report. In order to achieve adequate life with high climb and cruise engine performance, the engine takeoff thrust is reduced at inlet temperatures below 30°C (86°F) by limiting maximum fuel flow. This effectively flat rates the engine. Full engine thrust is obtained at higher temperatures but the thrust is reduced to about the 30°C (86°F) value at colder temperatures. The effect of limiting fuel flow is shown on Figure 12 which also shows the part power thrust at sea level is limited on a cold day. Altitude performance is not affected by the fuel flow limit because fuel flows under all conditions are below the limit at altitude.

Increasing turbine inlet temperature increases takeoff hot day thrust, and climb and cruise performance. The flat rating results in approximately a 3,000 hour engine life which corresponds to about 5 years between overhauls with the expected aircraft usage. This is lower than the goal for the T700-GE-700 engine which is 5,000 hours, but it appears to provide a beneficial tradeoff with improved performance for the general aviation aircraft.

Some of the important engine design performance parameters are shown in Table 5. Tables 6 and 7 are the standard and hot day rating tables for the engine. Figure 13 shows engine net thrust as a function of altitude at maximum climb and maximum cruise thrusts and 0.4, 0.6, and 0.8 Mach numbers. Figure 14 shows the specific fuel consumption (SFC) in the same way.

## ACOUSTIC CHARACTERISTICS

### APPROACH

The General Electric QCGAT engine nacelle configuration is shown in Figure 15. The acoustic analysis of the engine was conducted for the aircraft described in the Engine Selection and Application Section for the takeoff and approach flight characteristics given in Table 4 and Figure 6. Engine cycle parameters used to predict fan core and jet noise at takeoff, sideline, and approach powers are listed in Table 9. The acoustic features on which the QCGAT engine design is based are:

1. Fan Vane to Blade Ratio
2. Fan Vane to Blade Spacing
3. Inlet and Fan Exhaust Acoustic Treatment

Turbine noise is not considered to be a significant contributor to the overall noise signature of the engine because the LP turbine rotational speed of 13,000 rpm at approach is relatively high and the number of blades (60) is relatively large. Also, an empirically derived prediction procedure indicates that core combustor noise is not a significant contributor. General Electric experience with gear noise also indicates that the fan reduction gear noise will not be significant at the distances specified in the noise level requirements. Jet noise is probably the dominant source at takeoff and sideline conditions, for a treated engine. Fan noise is expected to be dominant at approach conditions.

### VANE AND BLADE GEOMETRY EVALUATION

The acoustic-mechanical design trade-off analyses which lead to an acoustic design for a single stage fan are affected by the ratio of the number of rotor blades to outlet guide vanes (OGV). Theoretical analysis and test results indicate that rotor blade wakes, passing through the stator, create radiated noise in the aft quadrant. That noise, which is probably the dominant source of aft quadrant noise radiation for the QCGAT engine fan nozzle, can be reduced by maintaining a large ratio of outlet guide vanes to rotor blades and by large rotor to OGV spacing. Figure 16 includes the correlated results of various test programs. The data shows the general effect of numbers of blades and vanes and the effect of rotor to OGV spacing on PNdB. Other trade-off parameters are the amount of acoustic treatment in the fan and fan nozzle duct, and noise shielding by the aircraft. The trade-off analysis for the QCSEE - Over The Wing (OTW) design resulted in a configuration with 28 rotor blades, 33 OGV which serve as struts and a 2-chord rotor-to-OGV spacing. This Configuration 1 on Figure 16.

Initially, the QCSEE - OTW design was scaled for the T700 QCGAT design. However, during the preliminary design phase of the QCGAT program, Task II, it was determined that the linear scale factor of 0.37 led to higher frequency tones in the T700 QCGAT design because of the increased fan speed. These frequencies lie in a higher NOY weighting regime of the noise spectrum and, therefore, lead to higher relative PNdB levels. Because it appears to be undesirable or impractical from the mechanical design standpoint to install large enough amounts of acoustic treatment in the smaller QCGAT engine to reduce radiated noise adequately and because the QCGAT aircraft installation will probably not benefit from aircraft shielding, as over-the-wing QCSEE installation does, it was decided to investigate two additional fan blading configurations. These are different from the QCSEE design only in the design of outlet guide vanes and struts. The three configurations analyzed are:

Configuration		Blades	OGV	Spacing
1	QCSEE OTW scale	28	33 vane struts	2 chord
2	T700 QCGAT Mod 1	28	56 vanes	2 chord
3	T700 QCGAT Mod 2	28	18 vane struts	3 chord

Configuration 2 has eight struts behind the OGV to carry the structural loads and services which are required. Configurations 1 and 3 both use the OGVs as struts. Figure 16 indicates that higher noise generation due to the small number of vanes in Configuration 3 is partially compensated for by the larger blade-to-vane spacing which is possible. However, Configuration 2, whose parameters are given in Table 10, provides about 2 PNdB improvement over the other configurations because of the larger number of OGVs. It is also the basis for a sound low cost mechanical design in the small size QCGAT engine, which, with acoustic treatment, will meet desired aircraft noise objectives.

#### ACOUSTIC TREATMENT EVALUATION

The nacelle shown in Figure 15 and Configuration 2 described in Table 10 were used to determine the noise reduction available from the installation of acoustic treatment on the fan frame outer wall between rotor and vanes, and in the fan nozzle duct aft of the struts on both outer and inner walls. In general, fan noise

Nominal Fan Duct Length = 16 in. (L), L/H = 2.35

H/ $\lambda$  Approach = 1.46

reduction was made. It is presented in Figure 17 for the approach power point and at takeoff and sideline conditions. Predictions of T700 QCGAT flight spectrums, front and aft max noise angles, were based on QCSEE-OTW spectrum predictions scaled down to QCGAT engine size. The reliability of these prediction methods has been confirmed by tests on the QCSEE-UTW (under-the-wing) configuration. The QCGAT spectrums were obtained for approach, sideline, and takeoff flight conditions. They include the 1/3 octave spectrum predictions of jet, core, and fan noise. The objective of this type of spectrum analysis is the determination of noise constituent PNdB values at the front and aft quadrant maximum angle noise locations. These PNdB values are summed, corrected for aircraft flight effects and used to determine EPNdB values for the aircraft. Front quadrant (inlet) noise reduction due to addition of inlet treatment was determined from empirical data presented in Figure 18.

**AIRCRAFT ALONE NOISE (NO ENGINE NOISE)**

Table 12 shows that the treated QCGAT engine is very quiet in comparison to current FAA rules. Since engine noise levels are forecasted to be low, it is desirable to determine whether aircraft alone noise could become the dominant flight noise contributor.

Figure 19. QCGAT at Takeoff Power - Constituent Bar Chart.

Figure 21. QCGAT at Approach Power - Constituent Bar Chart.

To calculate aircraft noise, a clean wing noise prediction model (ref. 1) was used to predict 1/3 octave spectra at various acoustic angles for the pass of a particular aircraft over the microphone. By assigning a typical flyover time history for the aircraft, EPNdB numbers were determined for a range of aircraft weights for the various FAA conditions.

The results are plotted in Figures 3 through 5, along with flight noise estimates of QCGAT and noise status of other aircraft. The figures also show the FAA current and proposed rules. It appears from these results that the T700 QCGAT engine may be sufficiently quiet that the aircraft alone noise will dominate the flight signature and prevent the achievement of lower radiated noise levels.

## EXHAUST EMISSION CHARACTERISTICS

Combustion system emissions levels predicted for the QCGAT engine cycle are based on GE12 demonstrator and TF34 engine test data. The QCGAT combustion system is identical to the T700-GE-700 combustion system which is a developed and refined version of the GE12 combustion system.

The test data was used to derive emissions correlation equations for each of the four EPA cycle conditions: Idle, approach, climb, and takeoff, and for each of the three major emission pollutants: carbon monoxide, unburned hydrocarbons, and nitrogen oxides. These correlation equations are similar to those developed for the NASA Experimental Clean Combustor Program.

One  $\text{NO}_x$  correlation was developed to predict the  $\text{NO}_x$  emissions at the low power conditions (Idle and approach) and a separate correlation was used to predict the  $\text{NO}_x$  emissions at the high power conditions (takeoff and climb). In the same way, different correlations were developed to predict the CO emissions at these two extremes of power settings. However, the  $\text{C}_x\text{H}_y$  emissions were satisfactorily correlated with a single equation.

The T700-GE-700 combustor dome design includes a central fuel injector with concentric reverse swirlers around each injector. Since that design is very similar to the design of the current TF34 combustor dome, recent TF34 engine emission test data were used to develop new correlation equations for the emission indices. These equations were corrected for residence time differences and solved to predict the emission indices for the QCGAT engine. In general, the agreement with the GE12 data is very close. At the Idle condition for the QCGAT engine, the correlations developed from the GE12 test data predict a CO emission index of 42.9 g/kg (lb/1,000 lb) of fuel, and the correlations developed from the TF34 test data predict a CO level of 43.2 g/kg (lb/1,000 lb) of fuel.

The results of emissions calculations for the T700 QCGAT engine are given in Table 13. The thrust and time spent at Idle, approach, climb and takeoff are the EPA, Class T1 Standard landing and takeoff cycle. Table 13 shows that, currently, the CO emission is above the EPA Standard. However, unburned hydrocarbons and carbon monoxide emissions will be reduced by using the sector burning techniques which have been applied in the CF6 and F101 emissions reduction program. In sector burning tests on those engines, a 47% reduction in CO emissions and 87% reduction in  $\text{C}_x\text{H}_y$  emissions were achieved by sector burning. As Table 13 indicates, this technique can be expected to bring QCGAT emissions within the EPA Standards.

**TABLE 13. ESTIMATED EFFECTS OF SECTOR BURNING**

## FAN DESIGN

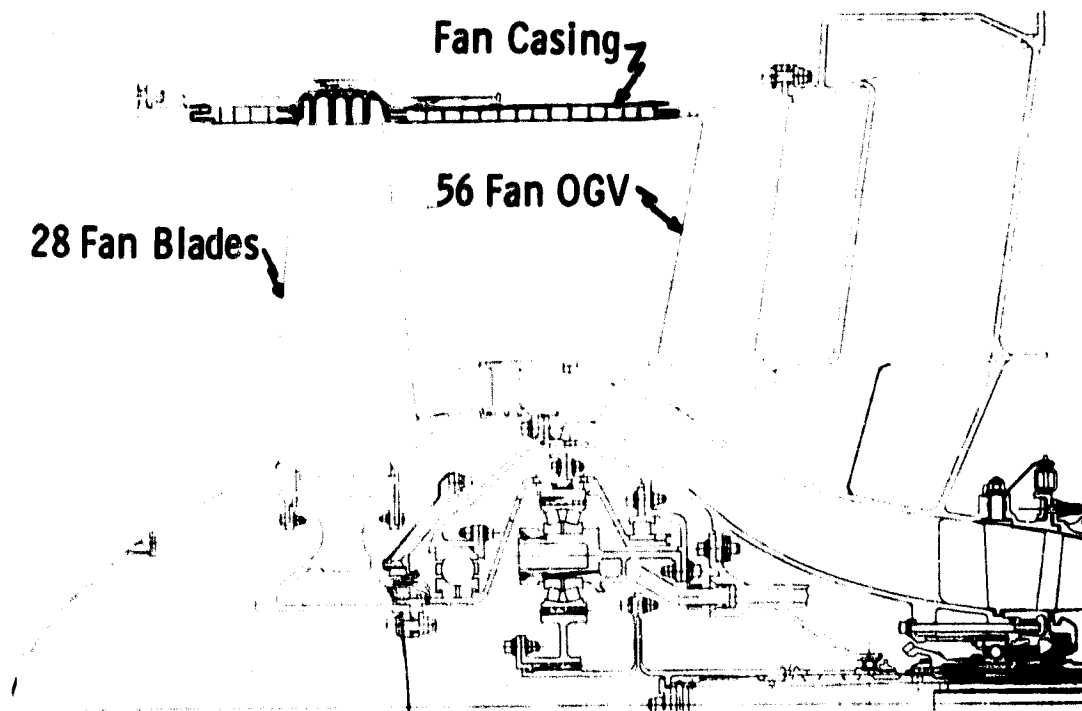

### AERODYNAMIC DESIGN

The QCGAT flowpath and single stage rotor, shown in Figure 22, are a 0.37 linear scale of the QCSEE - OTW design (ref. 2, 3, and 4). There are 28 rotor blades, 56 outlet guide vanes (OGVs) in the by-pass flowpath and the fan rotor to OGV spacing is 2 chords in order to reduce noise radiated by the fan to the aft quadrant as much as possible. To provide for structural loads and services, which are required, eight struts are located aft of the OGV. The aerodynamic design intent for the T700 QCGAT inlet, fan, by-pass duct, and fan-to-core passage is to make them a 0.37 linear scale of the General Electric QCSEE-OTW Design. The only major deviation is the by-pass OGV design which was changed by increasing the number of vanes for noise reduction and by providing separate structural struts aft of the vanes. See the Acoustical Characteristics section for a more complete discussion of the acoustic design.

A comparison between the important performance parameters at the QCSEE design point and at the QCGAT takeoff condition is:

Parameter	QCSEE Design Point	QCGAT Takeoff
Total fan flow	408 kg/sec (900 lb/sec)	50.0 kg/sec (110.3 lb/sec)
Pressure ratio - bypass flow	1.36	1.26
Pressure ratio - core flow	1.43	1.32
Bypass ratio	9.9	9.76
Corrected tip speed	358 m/sec (1175 ft/sec)	294 m/sec (964 ft/sec)

The fuel flow limit, discussed in the Performance section of this report causes the takeoff fan flow at sea level on a standard day to be lower than the scaled QCSEE flow which is  $0.37^2 \times 408 = 55.8 \text{ kg/s} = 123 \text{ lb/sec}$ .

**Figure 22. T700 QCGAT Composite Parts.**

## **ROTOR MECHANICAL DESIGN**

In the 28-blade composite fan design, the integral fan blade platforms made from 80% AS/20% Kevlar material weigh .204 kg (0.45 lb). If they were made of Ti-6Al-4V material, they would weigh .549 kg (1.21 lb). Full rotor weight for the composite design is 8.16 kg (18.66 lb), while a metal design would be 19.8 kg (43.74 lb) for the same number of blades, mainly because the disk is also heavier for titanium blades.

The primary advantages of organic matrix composites when compared with Ti-6Al-4V fan blades are lower cost and weight. Additional advantages of organic matrix blades are reduced weight of the supporting structures, reduced blade containment penalties, reduced secondary impact damage, low notch sensitivity, and high fatigue resistance.

Table 14 is a tabulation of the rotor mechanical design data. Figures 23 and 24 give the chord and  $t_m/c$  distribution versus percent span. Figure 25 is the QCGAT Campbell Diagram.

The composite fan rotor blade design is based on successful designs and manufacturing techniques developed for larger engines. General Electric has fabricated and tested over 200 TF39, F103 and QCSEE composite blades. These blades are the result of a broad base material selection program which has been conducted by General Electric to keep abreast of new material developments in

the composites field. Also, extensive programs to develop design methods, analytical techniques, and testing procedures for composite materials have been conducted at General Electric.

### **STATIC STRUCTURE DESIGN**

Figure 22 shows a cross section of the fan preliminary design, and Figure 26 shows components which are made of composite materials. The outer and inner bands and the vanes of the by-pass OGV are of graphite epoxy material. The OGV is made of eight sectors for ease of maintenance and to prevent local heavy damage to the OGV from causing replacement of the entire OGV section.

The blade containment structure consists of a laminate boron-graphite and epoxy shell encapsulating a continuous belt of Kevlar material. The design shown is for the composite blades, although an acceptable Kevlar containment structure for Titanium blades could be provided by increasing the Kevlar belt thickness. Table 15 gives the important design parameters of vane sectors, fan casing, and fan blades.

## ENGINE LIFE ANALYSIS

Allowable operating life for an aircraft engine is dependent on the cumulative damage to the most critical component because of operation over long periods of time at high engine speeds and temperatures. The most critical component in the T700-GE-700 is the Stage 1 blade of the high-pressure turbine which is rupture limited.

An engine life analysis based on the takeoff ambient temperature distribution shown in Figure 27, was conducted on the T700 QCGAT engine. The figure includes an estimated annual average distribution curve, derived from airline information and other sources such as MIL-STD-210B, and the proposed QCGAT distribution, which is more conservative. Increasing ambient temperature ( $T_2$ ) tends to increase turbine inlet temperature  $T_{4.1}$  for a given thrust rating. It also increases the temperature of compressor discharge air, which provides cooling for the hot section components, and therefore, reduces the cooling effectiveness of the system. If not considered in the life analysis, the effects of high  $T_2$  can cause premature failure of critical components. Table 16 shows the time spent in the important segments of four one-hour and two two-hour missions which were used in the engine life analysis. The most important segments are takeoff, climb, and cruise. Other segments do not contribute significantly to the damage sustained per flight.

Figure 28 shows the beneficial effect of flat rating on engine life. The calculations were based on the one-minute takeoff duration, one- and two-hour missions of Table 16. Figure 28 shows that engine life increases rapidly with decreasing  $T_2$  at temperatures lower than approximately  $30^\circ\text{C}$  ( $86^\circ\text{F}$ ). In that region,  $T_{4.1}$  is lowered by a fuel flow limit which has the effect of flat rating the engine below the turbine inlet temperature corresponding to a  $30^\circ\text{C}$  ( $86^\circ\text{F}$ ) day. Figures 29 and 30 show the effect of climb and cruise  $T_{4.1}$  on life. For these figures, the engine is flat rated at takeoff and the climb and cruise turbine inlet temperatures were held constant for the mission. The effect of  $T_{4.1}$  on life for missions with a 15-minute duration climb, with takeoff and cruise duration varied, indicates the strong effect of turbine inlet temperature on time-between-overhaul (TBO).

The results of the engine life analysis shown in Figures 28 through 30 indicate that 2700 to 3200 hours between overhauls are feasible for one-to-two hour missions if the engine is flat rated up to  $T_2 = 30^\circ\text{C}$  ( $86^\circ\text{F}$ ) and takeoff durations are one minute or less. If the QCGAT aircraft is in use for 600 hours per year, the TBO is about five years. This engine life is less than the T700-GE-700 goal of 5,000 hours with 15% and 20% of the time at rated  $T_{4.1}$  for the UTTAS and AAH aircraft, respectively. The shorter QCGAT engine life results from higher climb and cruise  $T_{4.1}$  for the T700 QCGAT than for the T700-GE-700. In the tradeoff between engine performance and life, the improved performance due to higher  $T_{4.1}$  results in a shorter but adequate five-year TBO.

### FAN LOW-PRESSURE TURBINE DESIGN

A review of T700 cycle data and a preliminary aero design analysis were made to determine the degree of compatibility of the present T700-GE-700 LP turbine configuration with QCGAT LP turbine requirements. The conditions for the analysis were:

1. Preservation of the present T700 flow path dimensions.
2. Design point at 10.7 km (35,000 ft) altitude and 0.7 Mach number.
3. LP turbine speed of 22,000 RPM.

On this basis design and off design velocity diagram calculations were made to determine the changes required in LP turbine vane and blade geometry. The results were:

1. The present T700 flow path is satisfactory for the T700 QCGAT engine. However, discharge absolute Mach numbers are in the range of 0.4 to 0.5 which is somewhat higher than the T700 Mach numbers.
2. At 10.7 km (35,000 ft) altitude and 0.7 Mach number exit, swirl angle is about  $10^\circ$ . At takeoff, it is close to zero.
3. Turbine blading should be modified.

The new LP turbine blading will have increased solidity in the second stage and increased gas turning angles. The following is a pitch line turning angle comparison:

	<u>T700-GE-700 Engine</u> (deg.)	<u>QCGAT Engine</u> (deg.)
First Nozzle	60.1	62.2
First Rotor	90.1	103.5
Second Nozzle	82.7	90.3
Second Rotor	80.6	81.4

This design increases blade loading by 25% and energy output by 36%. The increased output costs about one point in efficiency.

The gas exit angles, turning angles, loadings (Zweifel Numbers), and solidities at the more highly loaded rotor-blade root and nozzle-vane tip locations are given in Table 17. The comparison with the T700-GE-700 design indicates that changes in blade geometry and in second stage solidities leads to T700-QCGAT loadings which are similar to those of the T700-GE-700 LP turbine.

## GEARING

### FAN REDUCTION GEAR

The epicyclic speed reduction gearset which drives the fan is of the star configuration. It is similar in layout and arrangement to the QCSEE reduction gear with which it is shown in Figure 31. In the QCGAT application, a unit which has five branches has been chosen. The physical size of the gearset is governed by the size of the spherical double row roller bearings. Calculations indicate that a smaller bearing of this type would suffice. However, the bearing shown is the smallest size available in this country due to the limitations imposed by existing tooling. The gearset is envisioned as a bench assembly which is positioned into the engine forward frame during the final stages of engine assembly. The machinery concept and material selection provide a reliable flightworthy unit capable of being put into immediate production. Table 18 gives the important design parameters of the reduction gear whose design oil temperature is 116°C(245°F).

The gearset is driven by the LP turbine shaft by means of an adaptor shaft which contains a flexible coupling. The flexible coupling provides for radial flexibility to assure free-floating of the sun gear for proper load-sharing during operation. A simple locking means positions the sun gear axially for tracking, but does not otherwise offer restraint. The sun gear is driven by a spline coupling at the forward end of the adaptor shaft. The externally splined half of this coupling has a slight helix angle to account for shaft twisting and is lightly crowned for alignment under load and flexibility.

The free-floating sun gear meshes with and drives five star gears which rotate about fixed axes, serving as idlers between the sun gear and the ring gear. The star gear teeth are machined into and are integral with the outer races of the spherical double row roller bearings. This design concept has been applied successfully in the GE T64 turboprop planetary speed reduction gearset.

The ring or annulus gear is driven by the star gears and is free to float radially and axially within mechanical limits. An external spline at the center of its face and along its outer diameter engages a mating spline in the ring gear carrier. This spline coupling is designed with sufficient radial tooth proportions and clearance to allow for flexing of the ring gear during operation.

The star gear carrier is a machined casting which incorporates a cored lube oil manifold. It has five bearing posts to which the spherical double row roller bearings are fitted. The bearing support posts will be misaligned so that the sun star and star ring gear meshes are in alignment at operational load levels.

Tangential Driving Load - N (lb)			2,410	(541)	2,410	(541)

\*Design conditions were:

Gear loading - 141 kW (1900 hp)  
Speed - 20,600 rpm  
Heat rejection - 1.55 kW (53,200 BTU/hr)

Thus misalignment stresses and edge or corner load conditions exist only at low nonoperational torque levels and do not exist during operational modes when stresses are mainly due to drive loads. Also, the bearings come into alignment as load and speed increase. Thus, axial slipping is held to minimum during operation and allowed to go to a maximum at startup and coast down. This increases efficiency and bearing life.

The ring gear carrier also serves as the fan shaft. The carrier spans the epicyclic gear assembly and is driven by the ring gear through a spline coupling which is forward of its midflange. The carrier transmits the drive torque while supporting the fan induced thrust, gyro, LP, and radial loads. Bearings at each end support the carrier in the static casing structure which is attached to the engine forward frame.

Finite element computer programs are available to analyze the star gear carrier, star gear-bearing outer races, the ring gear carrier, and the housing or casing from a stress deflection viewpoint so as to allow the design to proceed with choices based upon engineering prediction.

Lubrication will be furnished by either MIL-L-7808 or MIL-L-23699 synthetic oil. The present concept is to lubricate the bearings through their inner races, taking advantage of the centrifugal fields to disperse the lubricant, and to oil spray both the sun-star and star-ring meshes. Oil scavenging and the use of and the positioning of appropriate shrouds to reduce windage will be studied.

#### POWER TAKEOFF (PTO)

The power takeoff which drives the accessory gearbox (AGB) will be a modification of that presently employed in the T700-GE-700 engines. A new design will be required because of a change in shaft angle. It is anticipated that the radial bevel gearshaft bearing and shimming of the present T700 can be utilized. Therefore, design and hardware changes will be restricted to the bevel gears and support structure. The overail location and mounting means of the T700-GE-100 will be retained.

#### ACCESSORY GEARBOX (AGB)

The accessory gearbox which is shown in Figure 32 located below the engine has been configured to drive five accessory pads shown in Figure 33. On the forward side are the starter-generator, alternator, and hydraulic pump. On the rear side are the main fuel control (MFC) and the lube and scavenge pump. The hydraulic pump and the lube and scavenge pump are driven by the same gearshaft. Pad speeds for the various accessories are the same as those now in use on the T700-GE-700 AGB.

**FRONT VIEW SHOWING:**

**CROSS SECTION SHOWING:**

**Figure 32. T700 QCGAT Nacelle Section Showing Accessory Gearbox.**

Input to and output from the accessory gearbox is afforded by a bevel pinion gearshaft which engages the PTO through the radial drive shaft. The bevel pinion mates with a bevel gear whose gearshaft also mounts a spur gear idler and is parallel to all of the other gearshafts in the gearbox. The bevel gearshaft forward end terminates in the starter-generator pad. The starter drive train components which are subjected to the heavy start torque levels are therefore at a minimum.

The remainder of the gearing consists of parallel axis spur gears and shafts common to AGB design practices with idlers where required for spacing and/or proper direction of rotation.

The gearbox is of "watch case" construction. The MFC and starter-generator are attached by Marmon clamps. The other accessories are mounted to their respective pads by means of bolts or studs and locknuts.

Figure 33. T700 QCGAT Nacelle Cross Section.

## QCGAT LUBE SYSTEM

The lube system for the QCGAT engine is essentially the same as that of the T700-GE-700 engine, except that additional oil flow and scavenging are provided for the fan reduction gear. Figure 34 shows the oil tank cross section and Figure 35 is a schematic of the lube system.

The T700 inlet particle separator, which acts as an air-oil cooler, has been removed for the turbofan and is replaced by a fan, reduction gear and front oil sum. Therefore, the lube system of the T700-GE-700 engine must be modified for the QCGAT engine.

The T700-GE-700 concept of a front frame structure with integral oil tank and air-oil cooling capability has been retained for the QCGAT engine. The oil tank is integral with the fan frame and consists of two annular cavities connected by 7 of the 8 frame struts. In this way, the entire frame structure operates at relatively uniform temperature and thermal induced stresses are low.

The surfaces of the tank are exposed to fan discharge and core engine inlet air streams and act as an air-oil cooler. Figure 36 shows a schematic of the fan frame and oil tank.

Analysis of the heat rejection requirements of the lube system were made by assuming several values of power loss in the reduction gear (.8%, 1.1% and 1.5% of transmitted power) and combining with the known heat rejection of the T700-GE-700. Takeoff and various flight conditions were considered to determine sensitivities of reduction gear loss and of the rejection capabilities of the fan frame surfaces. Fins on the surfaces in the fan discharge stream were also considered in order to increase heat rejection to the fan discharge stream and to reduce the temperature increase of the core engine inlet air stream.

Fins have not been included in the design described here in order to reduce complexity and cost of the frame, but do provide a means to improve engine performance in the future.

Figure 34. T700 QCGAT Oil Tank Cross Section.

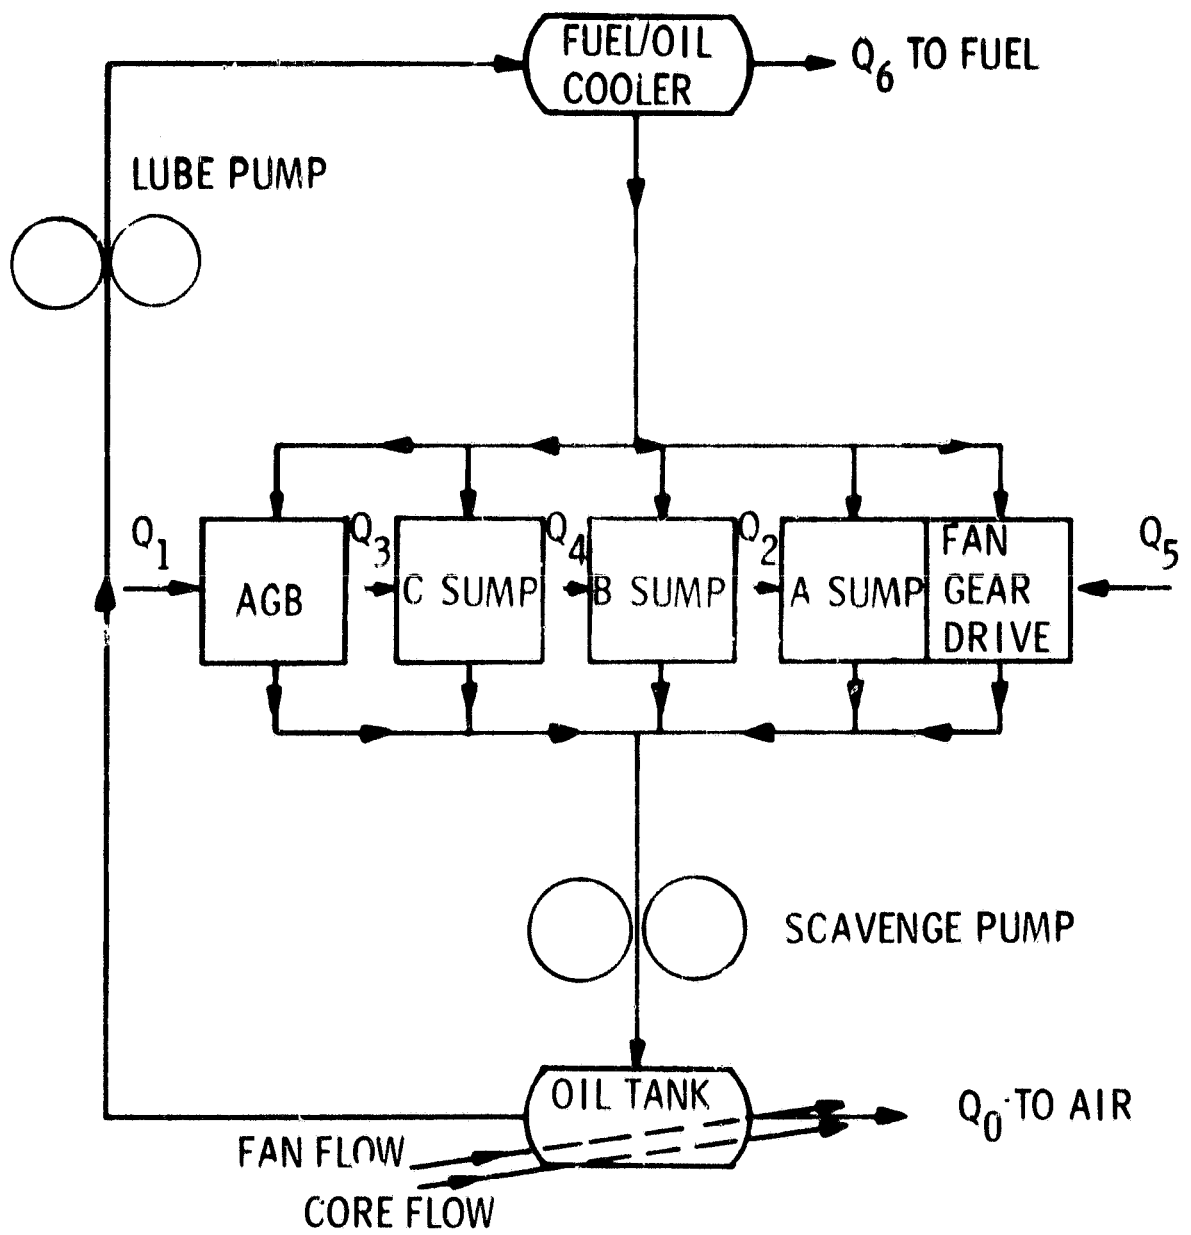

Figure 35. T700 QCGAT Engine Lube System Schematic.

Figure 36. T700 QCGAT Fan Frame Lube System Schematic.

The results of these analyses are shown in Figures 37 through 41.

Figure 37 shows that oil temperature increases with rising air and fuel temperatures. Figure 38 shows that the reduction gearbox provides an increasing percentage of the total heat rejected to the oil as power increases. Gearbox efficiency is most crucial at higher engine speeds - and is practically insignificant at Idle. Figure 39 shows the effect of air density and ambient temperature, both of which fall off with altitude and affect engine power. For the fuel, temperature is the dominant effect, as the lowered initial temperature more than offsets the increasing flow of heat from the oil. Figure 40 shows that fins improve the efficiency of the air-oil heat exchanger. By increasing the heat transferred at a given temperature, fins lower oil temperatures effectively. Without fins the maximum cooled oil temperature is about 240°F. All of the gearing is designed for that temperature.

Figure 37. Oil Temperature vs Ambient Temperature.

## CONTROLS AND ACCESSORIES

The T700-GE-700 control system is primarily hydromechanical with its turbine temperature control functions electrical. This control was investigated to determine its applicability to the T700 QCGAT turbopan engine. Also, a full authority digital electrical control was considered.

These controls must limit gas generator and fan rotor speeds. They limit turbine inlet temperature  $T_{4.1}$  by sensing and limiting the gas generator turbine discharge temperature  $T_{4.5}$ . In order to provide a flat takeoff rating, fuel flow is also limited. These functions are all available in the present T700-GE-700 fuel control. Also, Idle and minimum fuel flow settings are provided.

Acceleration and deceleration are the usual scheduled functions of gas generator speed inlet temperature  $T_{22}$  and compressor discharge pressure  $P_3$ . These are provided for in the present T700 control. However, changes to the 3-D cam, which schedules fuel flow as a function of  $T_{22}$ , will be required, since a different compressor inlet sensing device is necessary. The T700-GE-700 helicopter engine does not need a rapid response inlet temperature sensor, but the T700 turbopan engine will have rapid  $T_{22}$  transients during accels and decels because of the rapidly changing temperature rise across the fan. The engine will, therefore, have a correspondingly rapid response inlet temperature sensor, and that will lead to a different  $T_{22}$  schedule on the 3-D cam. There will be no fan inlet temperature sensor.

The present T700-GE-700 control provides adequate starting bleed, customer bleed for aircraft pressurization, and fuel flow for the T700 QCGAT engine. The engine will not require provisions for anti-icing, and torque sensing. For emission reduction, provision for shutting off fuel flow to the fuel nozzles at ground idle will be provided.

In order to keep the fuel control and its functions as simple as possible, the gas generator discharge temperature will be monitored by the pilot, who will use it to set climb and cruise conditions. Provision may also be made for the pilot to monitor fan speed. The present T700 control contains no provision for changing nozzle area. This function in the T700 QCGAT engine will be performed by the pilot, who will manually set the two-position fan nozzle in the open or closed position.

As engine size decreases, its control system cannot be decreased equivalently in weight or size. Therefore, a small engine tends to be overwhelmed by controls and accessories. An electric control would reduce the size of the control system.

A full authority digital control would be desirable for the T700 QCGAT engine. However, the development of such a system would be time-consuming and expensive, especially when compared to the present T700-GE-700 control, which is in production and which fulfills most of the needs of a general aviation aircraft. From this control, the anti-icing system, the load demand spindle, and torque sensor and circuitry will be removed. Provision for shutting off half of the fuel nozzles at Idle and a new fuel manifold will be added for emission reduction at Idle.

Most of the T700-GE-700 engine accessories can be used in the QCGAT engine. The fuel pump, ignition exciter, ignition alternator, igniters, gas generator turbine discharge temperature sensors and harness, and the fuel-oil cooler will not change. The required rotor speed pickups will not change.

Most of the accessory changes result from integrating the fan reduction gear and fan into the T700-GE-700 engine. Because of the fan, the accessory gearbox must be relocated and repackaged. The lube system must be enlarged because of the added load of the fan reduction gear. The size of the lube and scavenge pump and of the lube tank must be increased. Also, an 8 to 10 KVA starter-generator will be required. Other relatively small changes will be a new starting bleed valve and some changed linkages in the variable geometry system to connect the repositioned actuator, which is integral with the hydromechanical control, to the stator vane linkage.

## MOUNTING

The T700 QCGAT engine will probably be installed in nacelles mounted on horizontal pylons from the fuselage, on vertical pylons above the wing, or on vertical pylons below the wing. Engine mounts permit all of these installations. Figure 41 shows an isometric of the engine from the left side. Main mounts are provided in four locations on the outer surface of the fan frame, at 45 degrees above and below horizontal centerline. These are designed to take vertical, side, and thrust reactions.

The T700 core mainframe is provided with four rear integral mounting legs at horizontal and vertical centerlines.

The QCGAT engine can be mounted from any two main thrust mounts, and one rear mount. Figure 41 shows a typical mount arrangement, where left side main mounts and the left horizontal rear mount are used. Reactions at each mount are shown by arrows. For an installation of nacelle below the wing, the two upper main mounts and the top rear mount would be used.

Figure 41. Two Plane Mounting System.

## WEIGHT

The T700-GE-700 turboshaft engine base for the QCGAT engine has an established weight. The QCGAT engine uses the T700-GE-700 core and LPT parts (except airfoils). Weight estimates for the unique parts for the QCGAT engine have been made. Table 19 shows the results. A 7% margin for the unique parts has been included to account for tolerances and variations which might be included in detail designs as well as allowances for changes made to parts during a future engine qualification program. No margin is made for T700 common parts, since the qualification engine design has essentially been established. Total predicted QCGAT engine weight is 227 kg (500 lb).

In addition to the base engine with composite materials, adders are included for metal fan blades and OGV, which will continue to be considered as alternates while other General Electric technology programs evaluate composites. Table 19 also lists the separate weight of unique QCGAT parts and system adders.

## INLET AND NACELLE

The inlet has been designed for a throat Mach number of 0.6 to provide high levels of recovery and substantial flow margin before severe recovery loss is encountered. A throat Mach number of 0.6 also provides the maximum flow approach angle (angle of attack or crosswind) prior to the onset of separation inside the inlet. The recovery of this inlet is 0.997. Inlet contraction ratio expressed as highlight to throat diameter ( $D_{HL}/D_{THT}$ ) is 1.17, which provides angle of attack and crosswind capability of better than 50 degrees.

The T700 QCGAT mass flow ratio at 10.7 km (35,000 feet) and 0.7 Mn is 0.613. Figure 42 provides additive drag at that mass flow ratio. The figure shows that minimum drag occurs at forebody length/diameter ratio of about 0.55 and a highlight to maximum diameter ratio of approximately 0.8. Insufficient data is available to accurately determine minimum drag, but the trends indicate that the design chosen is virtually at the minimum drag point. Table 20 presents inlet-nacelle dimensions and compares design parameters with those of the QCSEE inlet.

Nacelle friction drag was calculated from flat plate, incompressible coefficients where wetted area is considered to be a cylinder of  $D = D_{max}$ , whose length extends from inlet lip highlight to fan nozzle trailing edge. The General Electric method of predicting boattail drag based on nacelle effective fineness ratio has been used to establish a boattail drag. The coefficient of 0.025 is based on free stream dynamic pressure and nacelle maximum cross section area ( $A_{max}$ ). Normalizing the total nacelle drag by  $Q$  and  $A_{max}$  results in the nacelle drag coefficient ( $C_{D\pi}$ ) = 0.066, which is assumed constant throughout the operating envelope of the engine.

The nacelle is perturbed locally at 6 o'clock in order to house engine accessories such as alternator-generator and main fuel control. This can be seen on the nacelle outline, Figure 43. A small, auxiliary inlet is located in the front "shark mouth" to provide accessory cooling air.

Figure 42. Nacelle Forebody Design Selection.

**Figure 43. Nacelle for T700 QCGAT.**

## EXHAUST DUCTS AND NOZZLES

### CORE TAILPIPE AND NOZZLE

The core tailpipe and nozzle are designed to efficiently diffuse the core exit gas from the existing T700-GE-700 turbine frame and provide smooth, rapid acceleration to the controlling area,  $A_8$ . The length of the tailpipe was determined by the fan duct and nozzle design, which maintains core cowl angles at no greater than 15 degrees.

Pressure losses in the tailpipe are the result of diffusion and friction on the tailpipe walls. Diffusion loss was taken from SAE Design Data for 1.71 area ratio diffuser with a 16.5 degree mean angle. Skin friction loss was calculated using the incompressible, flat plate relationship.

$$C_f = 0.455 / (\log R_{e_1})^{2.58}$$

A conic convergent nozzle was chosen for the core nozzle. This results in a configuration very similar to the TF34-GE-100 exhaust system, which provides high levels of performance.

### BY-PASS DUCT AND NOZZLE

The by-pass duct aft of the fan consists of a low area ratio diffuser to lower the average duct Mach number, constant area duct, and a two-position converging annular plug nozzle. The by-pass duct must be designed with doors to provide access to the core engine. Traditionally, the incorporation of doors results in steps and gaps in the flowpath, which cause pressure losses. These losses, along with losses caused by five fan frame struts ( $t_m/c = .203$ ), a pylon, and fins for the engine oil cooler drag, were included in the overall duct loss. In order to avoid large disturbances in the external flow field, the duct is designed with an accessory fairing in the 6 o'clock position. This allows the starter-generator, main fuel control, and several smaller accessories to be placed close to the engine centerline. Also at 6 o'clock there is a pylon through which the power take-off shaft (PTO), compressor geometry actuator, and all fuel, oil and electrical lines pass. The engine cross section, Figure 32, provides the qualitative detail of the duct. Figure 44 provides a more detailed description of the accessory fairing shape.

The length of the by-pass duct has been determined by trade-off studies considering both duct internal and nacelle external factors. Specifically, as the duct is shortened, both duct friction loss and nacelle friction losses decrease. If the fan

Services Pylon Cross Section (6 o'clock)

 Sound Suppression Treatment

Figure 44. QCGAT Nacelle - Lower Half.

cowl boattail closure and radius of curvature are independent of duct length, the boattail should have no influence on optimum duct length. As the design must provide a smooth flowpath from the by-pass nozzle to the end of the primary nozzle, the shorter the fan duct, the longer will be the scrubbed length of the core waist cowl.

Figure 45 presents the relative net thrust available at 10.7 km (35,000 feet) and 0.7 Mach number as a function of duct length. The figure indicates that overall engine performance improves as the duct is shortened. However, as the duct is shortened below a length of 101.6 cm (40 in), measured from fan case forward flange, the throat area interferes with the accessory fairing and nonsymmetric bluff base forms at 6 o'clock. Available base pressure data indicates that a base pressure coefficient ( $C_p$ ) of approximately 0.15 is appropriate at 0.7 Mach number. As can be seen in Figure 45, this causes a severe reduction in available net thrust. The aerodynamic optimum length shown on the figure is the shortest length with no bluff base. However, smooth closure of the nacelle and packaging of nozzle actuators require the nozzle throat to move slightly aft of the aerodynamic optimum. This is shown as the system optimum length at which 0.6% of available thrust is lost to create a viable, aerodynamically acceptable system design.

Because the duct loss is composed of diffusion, friction, and irregularities (step-gaps) the total loss is a function of the duct length and diffuser area ratio. Length by the tradeoff shown on Figure 45 was established at 134.6 cm (53.0 in). As area ratio increases, diffusion loss increases. However, increased diffusion results in lower duct Mach number, which leads to lower friction losses and step-gap losses.

Figure 46 illustrates this tradeoff in pressure loss as a function of duct diffuser area ratio. The diffuser design point area ratio of 1.35 is slightly greater than the minimum to provide for any flight conditions that may result in high corrected flows. The increment of pressure loss is insignificant.

The resulting axial area distribution shown on Figure 47 is generally smooth for both cruise and takeoff nozzle positions. Figure 48 presents average flow Mach number and wall static pressure distributions corresponding to the area distribution of Figure 47.

Favorable experience with the TF34-GE-100 fan nozzle has led to the use of a 15 degree core waist-cowl angle on the T700 QCGAT engine. This design provides the shortest possible cowl length consistent with low risk of premature separation of the fan discharge flow from the cowl. The TF34-GE-100 originally utilized a 10 degree cowl angle, but this was increased to provide additional core nozzle suppression which had favorable cycle performance characteristics.

A two-position, translating conic, annular plug nozzle is used. The outer wall is formed by a translating cone with a trailing edge angle of 15 degrees. The inner wall forms the plug portion and creates rapid convergence with the raised portion of the plug (see Figure 44). The nozzle actuation system is shown in Figure 49.

## EXPERIMENTAL PROGRAM

### INTRODUCTION

The experimental program plan describes the content, scope, schedules, cost estimate and risk assessment of a test engine specifically produced to demonstrate the performance, acoustical level, and emission level of the flight type production engine, previously described under the Engine Preliminary Design phase.

The test engine configuration, which differs in detail from the production engine, is also described. These differences will not compromise the objectives of the experimental program.

### ENGINE CONFIGURATION

The experimental engine cross section is shown in Figure 50. The principal objective of this engine design is to demonstrate the acoustical and emission levels as well as the performance characteristics of the production (flight type) engine. Accordingly, the design of the inner nacelle flow path includes flight type acoustical panels, front fan production design aerodynamics and the fan reduction gear box (also representing flight type production design).

Referring to Figure 50, the accessory gearbox (AGB) can be seen located at top rather than at the bottom as it would be on the flight type production engine, (see Figure 32 in the previous section). This accessory gearbox top location was chosen to enable the conventional T700-GE-700 engine AGB to be used. However, the flow passage obstruction for the production AGB is maintained, as is its location relative to the power takeoff shaft. This may be seen by referring to top view of Figure 51 and comparing it to bottom view of power takeoff and AGB location.

The fan nozzle (top view of Figure 51) is shown with an identical profile and aero flow path as the production design. Moreover, the axial motion from closed to open duplicates the production design. The actuators are externally mounted, see bottom view of Figure 50 to enable ready access during installation, rigging, and testing.

The standard T700-GE-700 core engine is used with the same low pressure turbine flowpath. The LP turbine blade and vane airfoils are modified the same as the flight design to match the aerodynamic requirements of the fan.

Figure 51. Comparison of QCGAT Experimental Engine Design vs QCGAT Production Design.

It can be seen in Figure 50 that the cowl may be replaced by two test bellmouths. The longer design represents the test cell bellmouth which is to be instrumented for engine performance testing. The shorter test bellmouth profile represents the actual cowl profile and contains acoustical panels permitting factory testing (without instrumentation) as well as the test in the outdoor acoustical facility.

The following list of components represent flight type hardware. Some of the parts represent the identical foil section as the flight design, but have different materials, e.g. the fan rotor blades are titanium. These materials, however, are flight type hardware and could be used in a final flight engine design. The fan exit guide vanes also are a different material, aluminum, which could be a final flight engine design.

Fan Rotor	Production engine aero design, except titanium blades.
Fan Exit Guide Vanes	Production engine aero design, except aluminum vanes.
Fan Frame	Production engine flowpath, except frame fabricated.
Fan Casing	Production engine flowpath design, except material will be aluminum.
Reduction Gear	Production engine design.
Power Takeoff	Production engine design, except drive shaft longer to mate with AGB.
LP Turbine	Production engine design.
Core Engine	T700-GE-700 core engine (CT7 will have been certified).
Fuel Control	T700-GE-700 engine control and fuel pump.
VG Actuation	Core engine linkage and actuator are flight type, connecting linkage for experimental testing only.
Acoustical Treatment	Production engine design.
Lube Pump	Production engine design.

The following components will be designed specifically for the experimental test program and to minimize program costs.

AGB	T700-GE-700 turboshaft unit will be used mounted on top of fan frame.
Lube Tank	Sheet metal tank, not configured to fit into flight nacelle, will be provided.
Oil Cooler	Cell water coolers will be provided instead of air-oil cooler integral with fan frame.
Nacelle	Same internal aero flowpath design as production engine, but without external surfaces and made of aluminum.
Fan Nozzle	Same aero design as production engine, with area change actuation, heavier construction than flight design.

Piping and valves for combustor sector burning will demonstrate required emissions, but will not be final design hardware (combustor is flight type).

## **PROGRAM DESCRIPTION**

The program scope includes design, fabrication (hardware procurement), component and engine testing to demonstrate performance, emissions acoustics, and mechanical integrity.

### **Design**

The design effort involves all design aspects required to add a geared fan to the T700-GE-700 core engine and to attach a nacelle and (adjustable) nozzle to the front fan frame for both factory and outdoor facility testing. Adapting the T700 AGB, controls and accessories to the redesigned PTO shaft will be accomplished for test purposes.

### **Hardware Procurement**

Hardware procurement of the unique components described above will begin with the early release of parts having long lead times especially the rough forgings,

castings, and fan reduction gear bearings. A list of the unique hardware and the number of sets required follows:

<u>Part</u>	<u>Sets</u>
Fan Blades	2
Fan OGV	1-1/2
Front Frame	1
Fan Casing	1
Core IGV	1-1/2
Nacelle, Cowl, Exhaust Nozzle	1
Exhaust Tailpipe	1
LP Turbine, Stage 1 and 2 Blades	1-1/2
LP Turbine, Stage 2 Nozzle	1-1/2
Unique Miscellaneous Hardware	1
Lube and Scavenge Pump	1 (unit)
Bellmouth	2 (units)

#### PROGRAM SCHEDULE

Figure 52 shows the program schedule. The schedule assumes go-ahead to occur July 1, 1976 - with shipment of engine to NASA on December 31, 1978. The program is planned to provide Design Release of critical hardware within the first three months on a priority basis. The long lead items such as blade and gear forgings will be released within the first month; then castings and fan gear reduction bearings a week or two later, and so on, to assure that all hardware will be received no later than the 16th month after go-ahead.

Since the same fan reduction gear which is to be used in component testing is to be later used in engine tests, the schedule is planned to complete component tests in the last quarter of 1977 with engine factory tests completed in the second quarter of 1978. This allows for a four month cycle to ship engine to Outdoor Facility in Peebles, Ohio, for acoustic testing (running the tests) and returning engine to factory. This permits a two month time period for the partial teardown and inspection of engine and minor reconditioning for prep-to-ship to NASA.

DESIGN RELEASE

SYSTEM DESIGN, EVALUATION & SUPPORT

COMPONENT TESTING

- COMBUSTOR, EMISSIONS
- FAN REDUCTION GEAR, BLADE/VANE VIB TEST

ENGINE TESTING

- ASSEMBLY AND INSTRUMENTATION
- FACTORY CHECKOUT RUN (10 HOURS)
- FACTORY PERFORMANCE & EMISSIONS (50 HOURS)
- OUTDOOR FACILITY-NOISE MEASUREMENT (20 HOURS)
- FACTORY PREP-TO-SHIP CHECKOUT (10 HOURS)

SHIP ENGINE TO NASA

Figure 52. QCGAT Experimental Engine Program Schedule.

## **COMPONENT TESTS**

**Three component tests are scheduled:**

- 1. Fan Reduction Gear Test.**
- 2. Combustor Emission Test.**
- 3. Fan Blade Vibration Testing.**

### **Fan Gear Reduction Test**

Test will be run at General Electric (Evendale, Ohio) facility. A drive stand will be modified to accept the gear reduction unit, (see Figure 53). Loading will be accomplished by having the gear set drive a water brake. After installing the instrumentation, the gear reduction unit will be tested both at light load and with full load.

### **Instrumentation of Gearset**

**The following instrumentation will be installed:**

- 1. Temperature:**
  - Bearing inner races (Star Gears).**
  - Lube oil in and out.**
  - Bearing outer races (Fan Drive Shaft).**
  - Gearbox casing at selected locations.**
- 2. Flow:**
  - Lube Oil-in.**
- 3. Vibration:**
  - Horizontal and vertical accelerometers.**
- 4. Speed:**
  - Tachometer.**
- 5. Noise:**
  - Suitable noise measuring instrument.**
- 6. Monitor:**
  - Magnetic drain plugs with electrical signal capability. SOAP analysis from oil samples.**

Figure 53. Fan Reduction Gear.

### Light Load Test

Initiate test with lube oil flow check. Initially start unit and rotate slowly while listening for abnormal sounds. Gradually bring unit up to 10% speed. Gradually apply light load (approximately 10% of full load). Note temperature readouts and stay at light load point for 15 minutes or until temperatures stabilize. Increase speed gradually to 20% speed, etc., up to and including 110% speed. Remove from test and partially disassemble for visual inspection.

### Full Load Test

Initiate test as in Light Load Test except that speed and then torque load are step increased in 10% increments from 10% to 110% of rated speed.

Data recorded will include:

- |                         |                         |
|-------------------------|-------------------------|
| 1. Percent Speed        | 5. Oil-Out Temperatures |
| 2. Percent Torque       | 6. Oil Flow Rate        |
| 3. Bearing Temperatures | 7. Horizontal Vibration |
| 4. Oil-In Temperatures  | 8. Vertical Vibration   |

Gear tooth contact pattern checks will be taken after 30%, 60%, and 110% speed data runs.

### Assurance Test (20 Hours)

This short test is to be conducted to verify the flight type integrity of the gear set without affecting its remaining life. The testing cycle selected represents a simplified general aviation flight schedule.

<u>Condition</u>	<u>Time (min)</u>
Full Power and Takeoff Speed	2
85% Power and Climb Speed	10
70% Power and Cruise Speed	90
30% Power and Descent Speed	18
TOTAL	120

Repeat cycle 10 times, totalling 20 hours.

### **Combustor Sector Burning Emissions Test**

Both visible emissions (smoke) and non visible emissions (gases, CO, CO<sub>2</sub>, NO, NO<sub>2</sub>) will be measured on a combustor component stand in accordance with ARP 1179 and ARP1256, smoke and gaseous emission procedures and EPA Federal Register Vol. 38 No. 136 Part II (July 17, 1973) Control of Air Pollution From Aircraft and Aircraft Engines, Emission Standards and Test Procedures.

Using system analysis cycle data, set combustor inlet conditions representing the 4 power settings:

1. Idle, from cycle data
2. Takeoff, 100% rated power
3. Climb Out, 90% rated power
4. Approach, 30% rated power

With conventional T700 combustor and fuel system, take smoke emissions and gaseous emission samples, analyze and compare with EPA standards.

With modified fuel supply system, explore sector burning and emissions together with exhaust temperature gradients. Analyze samples as before and compare with EPA standards.

If results are not as expected (better than standards) explore sector burning with other combinations of fuel nozzles.

### **Fan Blade and Vibration Testing**

Component Bench Tests will be run on:

1. Fan Blades
2. Fan exit guide vanes
3. Core inlet deswirl vanes

Vibration frequency checks (nondestructive) will be run on all fan blades and a large sample of vanes, approximately 30 of each, to establish design and manufacturing consistency over the full range of operating speeds.

**Stress Distributions (nondestructive) will be run on one sample of fan blade and of fan outlet guide vane by strain gaging various sections including base and root portion to determine end effects during both steady state and vibratory conditions.**

**Fatigue tests (destructive tests) will be run on four fan blades, six exit guide vanes, and six core inlet deswirl vanes to assure predicted margin over operating range of fan and engine.**

### **ENGINE TESTS**

**The experimental engine will be tested at the Lynn, Massachusetts, facility for aeromechanical data and performance, mechanical integrity, smoke and gas emissions.**

### **Facility Modification**

**These will consist of preparing a factory cell to accept and test the QCGAT Experimental Engine including its nacelle. The following list covers the cell modification and required test facilities:**

- |  |  |
|--|--|
| <b>1. Engine mounting dolly.</b>       | <b>6. Cell inlet modification blower added.</b>      |
| <b>2. Bellmouth, screen, brackets.</b> | <b>7. Air start system.</b>                          |
| <b>3. Throttle actuation system.</b>   | <b>8. Electrical jumpers and harnesses.</b>          |
| <b>4. Under cowl fire protection.</b>  | <b>9. Hoses, tubing and fittings.</b>                |
| <b>5. Exhaust adaptor.</b>             | <b>10. Electrical actuators (4) and motor drive.</b> |

### **Instrumentation**

**The instrumentation will include front fan blade rotating strain gages and slip ring assembly to measure vibratory stress levels in fan blades. Strain gages in fan outlet guide vanes and in core deswirl blades will be installed to measure their vibratory stress levels. Fan inlet and exhaust rakes and core engine inlet rakes will be installed to measure fan performance and fan plus engine performance. The pressure, temperature, and vibratory instrumentation required for component and engine performance will be installed. The list of instrumentation is as follows:**

### Front Fan Instrumentation

Rotating Strain Gages (12)  
Static Strain Gages (20)  
Inlet Rakes (4)  
Discharge Rakes (4)  
Inlet Rakes to Core (4)  
Vibration Pickups (8)  
Pressure Measurements, Kulites (12)  
Slip Ring Assembly and Adaptor  
Clearanceometers, Fan Blade Tip (2 at 90°)  
Traverse Actuators and Probes (3)  
Flow Path Static Pressures (50)  
Skin Thermocouples (8)

### Engine Operational Instrumentation

Operational Temperatures (15)  
Operational Pressures (15)  
Inlet Screen Thermocouples (40)  
Exhaust Smoke and Gas Emission  
Probes  
Position potentiometers  
Vibration Pickups (6)  
Exhaust Nozzle Position Indicator  
Skin Thermocouples (20)

### Fan Reduction Gear Instrumentation

Operational Temperatures (15)  
Operational Pressures (5)  
Chip Metal Detector  
Vibration Pickups and Installation (6)

### Factory Check Out Run

After engine has been installed in its test cell and instrumentation completed, it will be run to check out facility, instrumentation, and engine's mechanical operation. Approximately 10 engine test hours are expected to be run for this test.

### Front Fan Aeromechanical and Engine Performance Tests

The most sensitive instrumentation is the rotating strain gage and the slip ring assembly and readout. Consequently, this part of the test will be conducted first. Although the emphasis is on the front fan and its instrumentation, other data including fan reduction gear operation and engine performance will also be recorded concurrently.

Speed Lines: Operate engine at 60, 70, 80, 85, 90, 95, and 100% speed. Gather data (5 points) at each speed representing five different fan exhaust area settings.

Traversing: Operate engine at 85, 90, 95, and 100% speed (including design point). Take aerodynamic profile at fan discharge, fan inlet, and at core inlet.

This data will provide information on the aeromechanical performance of the fan as well as the engine's performance.

**Analysis of the data will determine the following parameters:**

- 1. Fan stall line (actual or indicated).**
- 2. Fan efficiency.**
- 3. Fan pressure ratio.**
- 4. Fan and engine airflow.**
- 5. Fan blade stress measurements.**
- 6. Fan, reduction gear, and engine vibrations.**
- 7. Fan reduction gear mechanical assurance; e.g., temperatures, vibrations, oil pressure within operational limits as determined on component stand.**
- 8. Engine thrust, SFC, operating line.**

#### **Estimated Performance Ratings**

Referring to Figure 54, note that the thrust versus fan inlet temperature curve is not fuel flow limited as in flight engine curve. This demonstrates the engine's full potential which is advantageous in an engine development program. Table 21 shows the experimental engine rating data with takeoff at the same  $T_{4,1}$  as hot day. Compare this data with previous data shown in Tables 6 and 7.

#### **Engine Smoke and Gas Emission Test**

Refer to Combustor Sector Burning Emission Test for required test procedure specifications. Utilizing the exhaust smoke and gas probes, the engine will be operated at four power settings.

- 1. Idle, from engine operation.**
- 2. Takeoff, 100% rated power.**
- 3. Climb out, 90% rated power.**
- 4. Approach, 30% rated power.**

With fuel supply (sector burning) system selected during combustor testing, take smoke and gaseous emission samples, analyze and compare with EPA standards.

This testing is expected to consist of 50 engine test hours and completes the performance and emissions testing for the experimental engine at the Lynn facility.

Figure 54. QCGAT Experimental Program Engine Estimated Thrust vs Fan Inlet Temperature.

**TABLE 21. T700 QCGAT ESTIMATED PERFORMANCE RATINGS****AT SEA LEVEL, STATIC, STANDARD DAY**

<u>Rating</u>	Net Thrust (Min.)		Specific Fuel Consumption (Max)		Measured Gas Generator Discharge Temperature	
	<u>N (lb)</u>		<u>kg/kNs, (lb/lb hr)</u>		<u>°C (°F)</u>	
Takeoff	10765	(2420)	.00951	(.336)	830	(1525)
Max Climb	9537	(2144)	.00940	(.332)	782	(1440)
Max Cruise	8945	(2011)	.00935	(.330)	760	(1400)
90% Max Cruise	8051	(1810)	.00932	(.329)	-	-
75% Max Cruise	6708	(1508)	.00937	(.329)	-	-

### Outdoor Facility, Acoustics

Install the engine at Site IVD, Acoustic Arena, (see Figure 55) at the Peebles, Ohio facility. Perform checkout run on engine to correlate performance with factory. Take measurements at the following operating conditions.

Test No. 1: With acoustical panels installed and with microphones on towers, operate fan engine from Idle to Maximum power in eight equal increments. Measure fan speed and stabilize for approximately one minute. Take reading. Repeat reading from maximum power to Idle in the same eight equal increments.

Test No. 2: With acoustical panels installed and with microphones located for near field testing, repeat Test No. 1.

Test No. 3: With solid panels installed, repeat Test No. 2.

Test No. 4: With solid panels installed, repeat Test No. 1.

This testing is expected to consist of 20 engine test hours and completes the outdoor testing.

### Factory Prep-to-Ship Checkout

After engine is returned to the factory, it will be subjected to partial teardown and inspection. It is expected that minor replacements of parts will restore the engine to its original condition, after which a performance verification run will be made (approximately ten engine test hours) and the engine will then be shipped to NASA.

### RISK ASSESSMENT

Referring to the risk assessment summary in Table 22, it can be seen that all potential problem categories are classified as low risk (indicated by "L" in the table). This, of course, was an objective in planning the experimental engine program.

These low risk assessments are based upon the aeromechanical performance predictability of the combination of having a developed core engine (T700-GE-700) together with scaled and proven unique parts (e.g. fan and reduction gear scaled from QCSEE). The required emission and acoustics levels of acceptability, moreover, will have been achieved prior to engine testing. For example, the combustor component test will optimize emissions - the QCSEE noise data will be available to optimize acoustics. The notes and comments referenced in the Recovery Action column of Table 22 briefly explain the straightforward corrective action to be taken in the event that an unexpected problem should arise.

Figure 55. Plan View of Peebles Site IV D Acoustic Arena.

TABLE 22. QCGAT EXPERIMENTAL ENGINE RISK ASSESSMENT

<u>POTENTIAL PROBLEM</u>	<u>SOURCE OF DISCOVERY</u>	<u>CONSEQUENCES</u>	<u>TECH. RISK</u>	<u>SCHEDULE IMPACT</u>	<u>COST IMPACT</u>	<u>PROB. OF OCCUR.</u>	<u>RECOVERY ACTION</u>
1. <u>PERFORMANCE DEFICIENT</u>							
a. <u>SFC</u>	Engine Test	Miss SFC Goal	L	L	L	L	(1)
b. <u>Thrust, Test</u>	Engine Test	Miss Thrust Goal	L	L		L	(1)
2. <u>EMISSIONS TOO HIGH</u>							
Combustor Sector Test	Comb. Stand	Miss Emission Goal	L	L	L	L	(2)
3. <u>NOISE LEVEL TOO HIGH</u>	Outdoor Engine Test	Miss Noise Goal	L	L	L	L	(3)
4. <u>FAN BLADE AERO-ELASTIC INSTABILITY</u>	Lab Blade Frequency Check	Temp. Restriction on Engine Operation	L	L	L	L	Select blades for frequency
5. <u>FAN GEAR REDUCTION OPERATING DEFICIENCY</u>							
a. <u>Temperature Rise</u>	Component Test	Modification Required	L	L	L	L	Apply windage baffles
b. <u>Vibration</u>	Component Test	Modification Required	L	L	L	L	Refine balance, or control bearing clearance,
6. <u>BLADE TIP AND/OR SEAL RUBS</u>	Engine Test with Sector Burning	Clearance Increase	L	L	L	L	(4)
7. <u>NON-FLIGHT DESIGN COMPONENTS</u>	Engine Test	Redesign	L	L	L	L	
Long PTO Shaft, T700 AGB Oil Cooler, Oil Tank, Actuators							
8. <u>LOW PRESSURE TURBINE AIRFOILS</u>	Engine Test	Miss Performance	L	L	L	L	(5)
9. <u>SINGLE ENGINE PROGRAM</u>	Engine Test	Delay in Schedule, Increased Cost	L	L	L	L	(6)

Note (1) Performance deficiency could be due to low component performance or due to high losses in nacelle and nozzle. Operate core at higher turbine temperature. Predicted performance for experimental engine includes margin for component performance variations.

Note (2) Emissions exceeding goals could be due to fuel sector schedule. Fix by changing number of operating fuel nozzles.

Note (3) Because of noise data availability for QCSEE, probability of occurrence is very low. Acoustic treatment surface area could be increased.

Note (4) Increase clearance in area where rub occurs by either reduced blade or seal diameter or "elliptical" machining of stator parts.

Note (5) Modifications to LPT airfoils will consist of small changes to airfoil stagger angles and camber to adapt to turbofan flow and RPM differences from turboshaft engine. Experience with T700, TF34, CF6, TF39 LP Turbines makes this very low risk.

Note (6) T700-700 Development program has adequate high time test experience on 12 engines to insure that a single engine QCGAT program is very low risk.

## APPENDIX

### ENGINE PERFORMANCE DATA

Net thrust, fuel flow and airflow are shown as functions of Mach number, and specific fuel consumption (SFC in lb/hp hr) as a function of net thrust on Figures 56 through 76. The performance curves are given at altitudes from sea level to 40,000 ft in increments of 10,000 ft. Each figure includes six part power settings. Sea level and 10,000 ft also have takeoff power.

Table 23 gives the engine performance parameters at altitudes from sea level to 45,000 ft in 5,000 ft increments. At each altitude, the engine performance is given at Mach numbers, within the flight envelope, in increments of 0.1. The nomenclature used in the performance tables is defined as follows:

<u>Computer Readout</u>	<u>Nomenclature</u>	<u>Units</u>
26 ALT	Altitude	ft
27 ZXM	Aircraft Mach Number	---
351 TAMB	Ambient Temperature	°R
279 PAMB	Ambient Pressure	psia
42 T1	Inlet Total Temperature	°R
41 P1	Inlet Total Pressure	psia
31 FN	Net Thrust	lbs
35 SFC	Specific Fuel Consumption	(lb/hr)/lb
